Abstract

The increasing in ageing population has drawn on the attention to the level of well-being among elderly. This study measured the level of well-being among elderly in Selangor. It was study conducted to determine how far factors such as personal factor, social participation, financial factor, neighborhood and the level of income influencing the well-being. A survey method was conducted to collect data using a total sample of 466 respondents living in rural and urban areas. In order to access the statistical significant differences between these two living areas on the well-being among elderly in Selangor, t-test analysis was used. In addition, multiple regression analysis was performed to measure the influence of the relevant factors to the elders’ level of well-being. The findings showed that all the factors had influenced the level of prosperity among elderly. However, income factor was not an essential factor in the welfare of old people. Therefore, the implication of this study suggested that the elderly must be provided with their personal and social needs to increase their level of well-being.

Keywords: Personal Factor, Social Participation, Financial Factor, Level of Income, Well-being

INTRODUCTION

The changes in the trend of population was influenced by the economic growth and development. Today, the trend of population shows the increasing in elderly people. This happened due to the rise of life expectancy and declining fertility rate. The declining in rising life expectancy and fertility rates resulting from a higher level of education, advanced technology and economic control. Developing countries usually will experience the rapid transition of the population trend. As a result, the increasing amount of ageing population had effected on economic growth globally, workforces, saving, pensions investment, living condition, consumption, and taxes.

In Malaysia, the changing in population trend issue is not very critical, as the country has not become an ageing nation yet. However, it was reported that the rapid growth of population in Malaysia may have consequences for an individual’s income, health and education and might as well as well-being.

In a meantime, Malaysia is facing several issues including rising cost of living, rising consumer inflation, rising debt, stringent credit terms, and slowdown in the economic activity. All of these situations are affecting the quality of life of the population in this country. Malaysia has used the Malaysian Well-being Index (MWI) (EPU, 2013) to measure the level of well-being and quality of life of the country. Well-being in the MWI refers to the physical, social and economic benefits that contribute to the improvement of the quality of life and the satisfaction of
individuals, families and communities (Malaysia's Well-being Index Report, 2013). However, there are no specific factors to measure the level of well-being among elderly in Malaysia.

LITERATURE REVIEW

Elderly

Elderly or older people refers to the individual with the age of 60 years old and above which have been mentioned in the United Nation World Assembly on Ageing in Vienna (United Nations, 1983). As well as in Malaysia, The National Policy on Senior Citizens defined elderly as those who are above the age of 60 years old (Bahagian Pasca Perkhidmatan, 2015).

Well-being

The research objective of this study is to measure the influencing factor to well-being among elderly. Personal factor, social participation, financial factor and neighbourhood were taking into account to measure their influence on the level of well-being among elderly in Selangor.

The well-being by (OECD, 2013) has yet no specific definition. The well-being is interchangeably used with the quality of life, happiness and life satisfaction. Meanwhile, according to Diener, Oishi, and Lucas (2015) and Sarracino (2010) it refers to the perspective or evaluation of people on their own experiences. The evaluation include asking people on the satisfaction of their needs, the feel of their existence in a social group, and the question on purpose in life and emotions.

Well-being is also a desirable human state that concerned with the objective and subjective assessment of well-being (La Placa, McNaught, and Knight, 2013). La Placa et al. (2013) explained the definition of well-being as a few domains containing range of social, economic and environmental forces. The domains that provide the resources and the contexts for the generation and maintenance of well-being at all levels of society.

There are literatures on factors associated with the well-being conducted since long time ago including the study of well-being for gerontology. Recently, it is a more significant influence with elderly in particular. Various studies were done to develop the understanding about factors associated with the welfare of older such as the study of antecedents and outcomes of activity profile (Morrow-Howell et al., 2014) and indicators of well-being in later life (Age UK's Index of Well-being in Later Life, 2017). The latest study assumed that the level of well-being of elderly was influenced by all the factors namely personal factor (Diener, Oishi, & Lucas, 2003; Green, Iparraguirre, Davidson, & Zaidi, 2017; International Wellbeing Group, 2013; Sharifah Rosida Syed Ali, 2012), social participation, income, neighbourhood and living areas.

Personal factor

It seems that there were studies on the effect of personal factor to the level of well-being among elderly. A previous study from Green, Iparraguirre, Davidson, and Zaidi (2017) refers to the main subject in personal factor including the living arrangements in old age, family structure and intergenerational support and care and education. The personal factors mentioned had associated with the well-being.
The living arrangement and family structure had influenced the well-being among elderly (Agrawal, 2012; Andrade & De Vos, 2016). The study found that the elderly who are living at least with one child or living alone would disturb their wellness and Chan, Malhotra, Malhotra, and Østbye (2011) claimed that the elderly to have depression symptom. Next, the intergenerational support and care is one of the personal factor that associated to the well-being among elderly (Lin, Chang, and Huang, 2011). This was supported by Tian (2014) which had suggested that the intergenerational support and care significantly associated with the well-being and mental health among elderly. Another past study by Lin et al. (2011) taking into account the components in intergenerational support namely living arrangement, intergenerational norms and intergenerational affection. Lastly education is the personal factor which linked with the well-being (Cachioni et al., 2017). The study claimed that the education had contribute for peoples’ participation in an activity to acquire the knowledge and form a social connections. Hence, it is very important to investigate the influence of personal factors on the well-being among elderly.

Social participation

The meaning of social participation by World Health Organization (WHO, 2012) as involving or working closely with communities, informing people with information, consulting people with provide feedback, collaborating by partnering with communities in making decision and empowering by ensuring the decision controlled by the communities had influenced their well-being. Meanwhile, Levasseur et al. (2015) claimed social participation is the part of needs of life for every people. Their study on social participation in aging literature had identified the level of the participation which are (1) connecting with people by doing an activity, (2) being close with people, (3) interacting without doing any activity, (4) doing an activity together with other people, (5) lend a hand to other people and (6) contributing to community. Social participation also refers to the social contacts, social activities and voluntary works done by an individual in a community (Hietanen, Aartsen, Kiuru, Lyyra and Read, 2016).

Social participation is one of the crucial determinant to the well-being among elderly. This statement was supported by the previous studies where social participation have an influenced to the positive well-being especially for the successful aging (Adams, Leibbrandt, and Moon, 2011). Their findings recommended that the social context for successful aging including the engagement with people around such as one or more family members, caregivers, neighbours and friends.

Current similar research resulted social participation associated with successful aging as well as the well-being among elderly. Douglas, Georgiou, and Westbrook (2017) used the concept of social contacts, voluntary works and social involvement refers for the social participation as the indicator of successful aging and quality of life. Being involved and interaction within the community is the key to increase psychological well-being.

Financial factor

Financial factor is important in order to prepare for the old age. Financial factor refers to the financial support, having financial asset and having any debt (Long, 2016). A study by Chan and Fah (2010) defined financial factor as financial issues, financial managements, financial knowledge and financial practices.
Financial factor is one of the determinant in subjective well-being among elderly. According to Finance Personal Research Centre (2014) financial situation had an impact to the well-being. The study explained that the elderly with financial difficulties experienced poor well-being compared to the elderly living in good financial situation.

As such in Malaysia, most of the older people facing the financial hardship (Tey et al., 2016). The study had determined that spouse and children financially supported the elderly. Therefore, the concern for the financial factors to the elderly had called out researchers to formulate or create data to make sure they live peacefully without worrying on their financial.

**Neighbourhood**

A study by Kasim, Ahmad, and Eni (2008) referred the neighbourhood to the facilities in the local area with considering the facilities’ contribution to sustain the communities. While, Azmi and Karim (2012) explained that neighbourhood by taking into account the accessibility of the community to basic community facilities namely local shop, school and playground. Therefore, this study defines the neighbourhood as refers to the services or facilities provided in a residence.

According to Finance Personal Research Centre (2014), having a good and safe neighbourhood, a comfortable house and nice living areas associated to the well-being of an individual in later life. Further, Koh, Leow, and Wong (2015) claimed that neighbourhood safety and accessibility to facilities were important to the elderly. Such evidences created concern for the neighbourhood factor to the subjective well-being among elderly.

**Level of income**

Income is a fundamental measure for the well-being of an individual (Fleche, Smith, and Sorsa, 2012). A study by Easterlin (2013) found that people with high level of income living happier than people with low level of income. This fact perhaps suggests that the level of income associated with the subjective well-being among elderly.

An evidence by Gildner et al. (2016) claimed that income appears to have influence on the well-being among elderly. The increasing level of income adequacy lead to the rise of the well-being. However, a study by Wyshak (2016) proposed that income was not a major determinant to the subjective well-being among elderly. The analysis in the study on older women proved income and well-being have no significant influence. Hence, this study is important to determine the influence of the level of income and the subjective well-being among elderly.

In short, various results from the previous studies on the factors which had influenced the well-being among elderly. However, Malaysia still has no specific index for the well-being among elderly as the indicator to be used for every relevant action related to the well-being. Thus, this study focused on the personal factors, social participation, financial factor, neighbourhood and level of income as the determinants that affected the well-being among elderly.
Living areas

This study explores the issue on the living areas to the well-being among elderly. Numerous literature on the living areas namely urban area and rural area to the well-being. According to Lawless and Lucas (2011), the living areas refers to the accessibility to local services, social participation, housing cost and environment of the living areas including cleanliness, peacefulness and the safety of the surroundings. They claimed all of these factors to be associated with the quality of life.

Brereton, Bullock, Clinch, and Scott (2011) investigated that people living in the rural areas were more satisfied with their living. Although the local services were limited there, they still enjoy living in peace and quiet rural areas. In Malaysia, ageing in place commonly in rural areas (Hamid, 2015). The study determined that there must be safe living area or neighbourhood and worship places as the fundamental conditions for ageing in place.

Thus, there is still lack of research on the living areas to the level of well-being on elderly unless the determinants of subjective well-being takes into account. This concern to determine the level of being among elderly to the living areas either lining in urban areas or rural areas.

METHODOLOGY

This study used a set of questionnaire using Likert scale to measure the variables of this study. The research instruments were comprised three parts, namely part A, B and C. Part A covered the information on the demographic profile of respondents. Meanwhile, part B included the items on the level of well-being among the elderly. Lastly, part C consisted on the variables, which are a personal factor, financial factor, neighbourhood and the level of income. The items were adopted with modifications to suit the understanding of the information of well-being among elderly.

A number of 466 respondents at the age 50 years old and above were randomly selected from four districts in Selangor which were Petaling, Klang, Sabak Bernam and Hulu Selangor. Initially, the analysis for this study had implemented descriptive statistic to measure the level of well-being among elderly in Selangor. Next, in order to assess the extent to which of the factors explained the well-being, the analysis of regression analysis was conducted. Hence, here is the regression model to test the influence of personal factor, social participation, financial factor, neighbourhood and the level income to the well-being among elderly:

\[
WB = \alpha + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + e
\]

whereby:
\[
WB = \text{the level of well-being}
\]
\[
\alpha = \text{constant}
\]
\[
\beta_1 = \text{regression coefficient for } X_1
\]
\[
\beta_2 = \text{regression coefficient for } X_2
\]
\[
\beta_3 = \text{regression coefficient for } X_3
\]
\[
\beta_4 = \text{regression coefficient for } X_4
\]
\[
\beta_5 = \text{regression coefficient for } X_5
\]
\[
X_1 = \text{personal factor}
\]
X₂ = social participation  
X₃ = financial factor  
X₄ = neighbourhood  
X₅ = the level of income  
e = Error

Lastly, t-test analysis was used to identify the differences between urban areas and rural areas to the level well-being among elderly in Selangor.

FINDINGS

Descriptive Analysis

Results of descriptive analysis in table 1 shows the sample of 466 respondents. There were 40.1% male respondents and 59.9% female respondents. Over 80% of the respondents were between the ages of 50 to 59 years old. Meanwhile, about 12.4% at the age of 60 to 69 years old and 2.8% of the respondents at the age 70 years old and above. On the other hand, there were 59.9% of the respondents living in rural areas and 45.7% of the respondents living in urban areas. The descriptive analysis also revealed that most of the respondents (61.8%) have earned the income in less than RM4000. It was about 18.9% of the elderly received income between RM4 001 to RM6 000, while it was about 10.7% of them made in a range of RM 6 001 to RM8 000 and it was very least which 8.9% of the elderly had earned RM8 001 and more.

Mean analysis

To measure the level of well-being among elderly in Selangor, mean analysis was used.

Table 2 shows the level of well-being among elderly in Selangor. Based on the scale of measurement, the level of mean score between 1 to 2 the level is low, the mean score between 2 to 3 the level is moderate and the mean score between 3 to 4 the level is high. Thus, the elderly living in the reasonable level of well-being.

Regression analysis
Regression analysis was undertaken to measure the independent variables that influence the change in the dependent variable. In this study, multiple linear regression was used to measure the overall influence of the factors to the well-being among elderly in Selangor. All the outliers’ cases have been sorted out before the data to be tested for regression analysis.

</tr>
</tbody>
</table>

R² = .678
F-value = 190.615

Table 3 shows the result from the regression analysis. The value of R-squared was 0.678, which indicated that 67.8% of the variance in the well-being among elderly was explained by personal factor, social participation, financial factor, neighbourhood and the level of income. The result also clearly revealed significant values on the personal factor, social participation, financial factor and neighbourhood. Based on the beta values as the four significant variables, the most influence on the well-being among elderly in Selangor was neighbourhood ($\beta = .387, p = 0.000$), followed by the personal factor ($\beta = 0.321, p = 0.000$), financial factor ($\beta = 0.122, p = 0.000$) and lastly social participation ($\beta = 0.113, p = 0.006$). As for the level of income ($\beta = 0.040, p = 0.174$) indicated not significant. Thus, all the factors except for the level of income have the influences to the well-being of the elderly.

T-test analysis
A t-test analysis was used to access the statistically significant differences between living areas; urban areas and rural areas on the level of well-being among elderly in Selangor.

The result shows significant differences between living in urban areas and rural areas, where p<.05 (see Table 5). As in table 4, the mean values show that respondents who are living in urban areas are higher than the respondents who are living in rural areas. Thus, the result indicates that the elderly who are living in urban areas are more well-being than living in the rural area.

CONCLUSION

The personal factor, social participation, financial factor, neighbourhood and the level of well-being had demonstrated significant influences on the well-being among elderly in Selangor. The result shows neighbourhood had influenced the most on the well-being. It is important to have neighbourhood with medical services, transportations and shopping facilities, prior concerned for the well-being among elderly (Green et al., 2017). Moreover, Hamid (2015) claimed the fundamental conditions for ageing in place were having security in neighbourhood and the existence of worship places. Hence, it is essential to have services and facilities in the neighbourhood for the elderly.

Besides, this study found that there is no significant influence of the level of income on the well-being among elderly in Selangor. As stated by Easterlin (2013), the increasing in the level of income does not increase the well-being. However, the elderly are commonly having poor health and vulnerable which they need an adequate income to pay for their health services (Wyshak, 2016). Wyshak (2016) stressed that better health strongly associated with higher level of income.

However, income appears to influence the well-being in the long term (Diener and Biswas-Diener, 2002). According to Easterlin (2013), the well-being does not increase as income goes up. Moreover, the elderly are vulnerable to disease and commonly have poor health. Income inequality affect their well-being as they have inadequate income to pay for their health services. Instead, better health associated with higher income (Wyshak, 2016).
On the other hand, the level of well-being among elderly who are living in urban areas higher than living in urban areas. The result supported by numerous research, which claimed that the elderly living in rural areas experienced the lower level of well-being as compared to the urban areas. This due to the fact that the rural commonly have limited access to facilities and services as compared to the urban areas (Baernholdt, Yan, Hinton, Rose and Mattos, 2013; Requena, 2016).

As a conclusion, this paper provides evidence and information regarding the influences of subjective well-being and income to the well-being level among elderly in Selangor. Therefore, the present study suggests that the elderly must be provided with their needs to increase their level of well-being.
