Abstract

The ability of athletes to use psychological maturity, especially motivation, is an effective effort to achieve maximum performance in every sport. This study aims to adapt the Sport Motivation Scale-II (SMS-II) scale into Indonesian. The subjects of this study were 32 students from the Special Sports Class at Yogyakarta 13 Public Middle School, with 21 male and 11 female students. The findings in this study are that the Indonesian version of the SMS-II scale has good construct validity because it matches the underlying construct and has good reliability values. Thus, the Indonesian version of the SMS-II scale can be used to measure students' sports motivation in the context of research and practice.

Keywords: adaptation, motivation, SMS-II.

INTRODUCTION

Motivation has a big part in the world of education, especially physical education. Many studies suggest that motivation is closely related to academic achievement (Facturahman & Cholik, 2014). The success of athletes in various aspects of life is not only influenced by physical quality, technique, and tactics, but is influenced by mental quality. Mental skill is a very important factor because mentality is one of the predicting variables for an athlete's success in living his life (Thomas & Fogarty, 1997). As long as an athlete displays their performance, motivation is an important part of the psychological variable that leads the athlete to success. The ability of athletes to use psychological maturity, especially motivation, is an effective effort to achieve maximum performance in every sport. Motivation is defined as the main impulse that drives a person to behave. Motivation is defined as considerations triggering somebody to undertake a task and determine direction, intensity, and persistence of specific behavior based on tasks (Buckworth, Lee, Regan, Schneider, & Diclemente, 2007).

The process of achieving success in sports demand seriousness of athletes in undergoing an exercise program. Such conditions often make the athlete bored with training

ISSN: 2232-1918 / eISSN: 2600-9323 https://ejournal.upsi.edu.my/journal/JSSPJ

program routine that tend to be monotonous and less varied. Therefore, it is important for someone involved and participate in sports to have both intrinsic and extrinsic motivation. Intrinsic motivation is related to someone's participation in a particular activity for their feelings of fun, pleasure, excitement, and satisfaction. Meanwhile, extrinsic motivation has something to do with rewards such as money, trophies, social approval and punishment avoiding (Vallerand, 2004). This opinion confirms that intrinsic motivation is reflected in the implementation of activities that are always based on feelings of pleasure, joy, and satisfaction. Extrinsic motivation for someone to participate in sports activities is always based on something to be achieved that is extrinsic such as gifts in the form of money, trophies, or public recognition.

Cases that arise in the extrinsic factor of sports often dominate increasing their intrinsic motivation. Extrinsic motivation is focused on performance outcomes which tend to make athletes less interested in achieving success, athletes feel anxious, and difficult to overcome failure (Hatch, Thomsen, & Waldron, 2017). This situation will have a negative impact on the pattern of sports coaching, especially coaching young athletes. Athletes want to practice if given something even though external factors are not everything to do something best. Therefore, as an effort to avoid this, intrinsic motivation needs to be built in such a way as a basis for building athlete commitment to do the best thing, as well as providing confidence that something extrinsic is not everything in achieving something that is best in life.

Research in a company showed 63% of people will continue to do work and practice, because it is based on extrinsic factors in the form of money. However Aldag and Brief (1979) explain "money is something of importance for employees if they make it a final objective, yet it cannot fulfill everyone's needs and desires". Therefore, there needs to be an understanding in the athlete that the extrinsic factor is not the only thing that makes people feel satisfied in meeting all their needs and to do something better.

Motivation will function properly if there is fuel or driving source. One of the fuels the body needs is hormones. The hormones needed in carrying out activities are the hormone serotonin and the hormone dopamine. Both of these hormones function as neurotransmitters (signal carriers) that will be produced when a stimulus occurs to brain cells. In another phrase explained, "the hormone serotonin is a hormone of happiness that will regulate mood and prevent depression in a person. Hormone dopamine is a pleasure hormone that is released when a person tries to reach a goal. This hormone will motivate someone to work hard to achieve goals and make someone become more alert and focused on the task to be achieved (Desideria, 2015).

To determine student motivation, a measurement of motivation needs to be done. Measurements made must be valid and reliable. Valid and reliable measurements can be obtained when the presentation of the measuring instrument is carried out in a standardized manner and the measuring instrument has satisfactory psychometric properties (Azwar, 2015, 2017). So far, the measurement of sports motivation uses a variety of measurement tools. The measuring instrument is considered valid and reliable by looking at some psychometric properties such as reliability and item discrimination. This is quite simple because it does not include other psychometric properties that can actually provide a picture of the validity of the

ISSN: 2232-1918 / eISSN: 2600-9323 https://ejournal.upsi.edu.my/journal/JSSPJ

measuring instrument. In addition to simple psychometric properties, most motivational measures include linear measurement. A linear measuring instrument is a measure that views the underlying variable as a continuum from low to high values. The measurement results of this linear measuring instrument will find the high and low motivation of students to go to school. This becomes a limitation on measurement.

The measuring instrument cannot provide comprehensive information about students' motivation in sports. As for a measuring tool that provides comprehensive and standardized information and is widely adapted in several countries, the measuring instrument is Sport Motivation Scale-II (SMS-II) developed by Pelletier et al (2013). Ocal & Sakalli (2018) in their research that adapted the SMS II scale to the results of their research showed that the Turkish version of Sports Motivation Scale II is a conceptual and structurally valid and reliable measurement for Turkish athletes. Results of Li (2015) indicate that CSMS-II is considered to be reliable and generally valid for use with Chinese university athletes.

METHOD

SMS-II Scale Adaptation Process

The process of adaptation of the SMS-II scale into Indonesian follows the guidelines put forward by Purwono (2010). There are three stages in the adaptation process. First, study the extract with several experts. This stage is carried out to ensure that the extracts are relevant to the cultural context in Indonesia. The second stage is the translation that is done with the forward translation design. The translation is carried out by a team of translators who are competent in doing English-Indonesian translations and students who understand the theory. The translation scale was tested on a preliminary study to ascertain how easily the scale was understood and how well the subject's responses on the scale were. The preliminary study involved 14 students of the Special Sports Class at SMP Negeri 13 Yogyakarta. Students are asked to respond to all statements and assess how easy each point is to be understood. This process resulted in an Indonesian version of the SMS-II scale that was easy to understand and in accordance with the expected response. In the third stage, the Indonesian version of the SMS-II scale was tested to obtain validity and valid reliability.

Subject

The subjects of this study were 32 students from the Special Sports Class at Yogyakarta 13 Public Middle School, with 21 male and 11 female students. The subjects in this study consisted of various types of branching in the Special Sports Class at SMP Negeri 13 Yogyakarta.

Instrument

Arikunto (2010) stated that the research instrument is a tool used and selected by researchers in collecting activities so that the activity becomes systematic and facilitated. The instrument in the study was an adaptation of Sport Motivation Scale-II (SMS-II) developed by Pelletier et al (2013). The instrument adapted has 4 alternative answers, namely: Strongly Agree (SS), Agree (S), Disagree (TS), and Strongly Disagree (STS). Hadi (1991) explained that the modification of the Likert Scale by omitting the category of answers in the middle has three reasons, as follows:

ISSN: 2232-1918 / eISSN: 2600-9323 https://ejournal.upsi.edu.my/journal/JSSPJ

- a. The category of doubt has a double meaning and can be interpreted as not being able to decide and provide answers.
- b. The category in the middle raises the tendency of answering to the middle (central tendency effect) especially for those who are hesitant over the direction of the tendency of answers.
- c. The SS-ST-TS-STS category is to see the tendency of the respondents' opinions, towards agreeing or disagreeing. The answer category in the middle will eliminate most of the research data thereby reducing much of the information that can be captured from the respondents.

Data analysis

The classical approach was used to analyze the data of this study. Psychometric properties to be analyzed are the reliability and validity of the extract. Reliability was obtained through internal consistency using the Cronbach's Alpha formula. The validity of the construct was tested through correlations between dimensions that will form a simple pattern.

RESULRS AND DISCUSSION

Validity test

Arikunto (2010) states that "validity is a measure that shows the levels of validity or validity of an instrument". The value of rxy obtained will be consulted with the price of the product moment at the 0.05 significance level. If rxy> rtab, the item is declared valid. The calculation uses SPSS 20. The results of the instrument validity test in table 2 are as follows:

Tabel 2. Hasil Uji Validitas Instrumen

Butir r hitung		r tabel (df 32;5%)	Keterangan		
01	0,467	0,339	Valid		
02	0,849	0,339	Valid		
03	0,455	0,339	Valid		
04	0,818	0,339	Valid		
05	0,797	0,339	Valid		
06	0,592	0,339	Valid		

ISSN: 2232-1918 / eISSN: 2600-9323 https://ejournal.upsi.edu.my/journal/JSSPJ

07	0,583	0,339	Valid		
08	0,640	0,339	Valid		
09	0,671	0,339	Valid		
10	0,888	0,339	Valid		
11	0,911	0,339	Valid		
12	0,592	0,339	Valid		
13	0,600	0,339	Valid		
14	0,900	0,339	Valid		
15	0,671	0,339	Valid		
16	0,904	0,339	Valid		
17	0,849	0,339	Valid		
18	0,603	0,339	Valid		

Based on the results of the validity test analysis in table 2 above, it shows that out of 18 items indicate that all items are valid. That is because r count> r table, so 18 items are declared valid.

Reliability test

Instrument reliability refers to an understanding that an instrument can be trusted enough to be used as a data collection tool because the instrument is already good (Arikunto, 2010). Item reliability analysis is only performed on items that are declared valid and not all items that have not been tested. To obtain reliability using the Cronbach Alpha formula (Arikunto, 2010). Based on the analysis results, the instrument reliability test results in table 3 were as follows:

Table 3. Reliability

Table 5: Remability					
Cronbach's Alpha	N of Items				
0.946	18				

Based on the reliability test results table above, it shows that the SMS-II instrument is reliable, with a reliability coefficient of 0.946 so the instrument is feasible to be used as a measure of sports motivation. The validity tested in this study was the validity of the extract. The validity of the construct in this study drawn from the research of Vallerand (1992) who found a simple pattern on correlations between dimensions. The closer the correlated dimensions are, the higher the correlation value, conversely the further the correlated dimension, the lower the correlation can even be a negative correlation.

In the reliability test, the Indonesian version of the SMS-II scale has a value above 0.7. Azwar (2015) explains that the reliability value of 0.7 is good for reliability on the scale used with the aim of conducting research. Reliability values ranging from 0.7 to 0.8 can also be used for research and practice purposes. Thus, it can be said that the reliability of all dimensions in the Indonesian language version of AMS is quite satisfying and can be used for research and practice purposes.

CONCLUSION

The findings in this study are that the Indonesian version of the SMS-II scale has good construct validity because it matches the underlying construct and has good reliability values. Thus, the

ISSN: 2232-1918 / eISSN: 2600-9323 https://ejournal.upsi.edu.my/journal/JSSPJ

Indonesian version of the SMS-II scale can be used to measure students' sports motivation in the context of research and practice.
